

Fibre Channel Management MIB

Status of This Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects for information related to the Fibre Channel.

1. Introduction

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects for information related to the Fibre Channel.

2. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIV2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

3. Short Overview of the Fibre Channel

The Fibre Channel (FC) is logically a bidirectional point-to-point serial data channel, structured for high performance capability. The Fibre Channel provides a general transport vehicle for higher level protocols such as Intelligent Peripheral Interface (IPI) and Small Computer System Interface (SCSI) command sets, the High-Performance Parallel Interface (HIPPI) data framing, IP (Internet Protocol), IEEE 802.2, and others.

Physically, the Fibre Channel is an interconnection of multiple communication points, called N_Ports, interconnected either by a

switching network, called a Fabric, or by a point-to-point link. A Fibre Channel "node" consists of one or more N_Ports. A Fabric may consist of multiple Interconnect Elements, some of which are switches. An N_Port connects to the Fabric via a port on a switch called an F_Port. When multiple FC nodes are connected to a single port on a switch via an "Arbitrated Loop" topology, the switch port is called an FL_Port, and the nodes' ports are called NL_Ports. The term Nx_Port refers to either an N_Port or an NL_port. The term Fx_Port refers to either an F_Port or an FL_port. A switch port, which is interconnected to another switch port via an Inter Element Link (IEL), is called an E_Port. A B_Port connects a bridge device with an E_Port on a switch; a B_Port provides a subset of E_Port functionality.

Many Fibre Channel components, including the fabric, each node, and most ports, have globally-unique names. These globally-unique names are typically formatted as World Wide Names (WWNs). More information on WWNs can be found in [WWN1] and [WWN2]. WWNs are expected to be persistent across agent and unit resets.

Fibre Channel frames contain 24-bit address identifiers that identify the frame's source and destination ports. Each FC port has an address identifier and a WWN. When a fabric is in use, the FC address identifiers are dynamic and are assigned by a switch.

4. MIB Overview

This MIB contains the notion of a Fibre Channel management instance, which is defined as a separable managed instance of Fibre Channel functionality. Fibre Channel functionality may be grouped into Fibre Channel management instances in whatever way is most convenient for the implementation(s). For example, one such grouping accommodates a single SNMP agent having multiple AgentX [RFC2741] sub-agents, with each sub-agent implementing a different Fibre Channel management instance. To represent such multiple Fibre Channel management instances within the same SNMP context (see section 3.3.1 of [RFC3411]), all tables in this MIB are INDEX-ed by fcmInstanceIndex, which is defined as an arbitrary integer to uniquely identify a particular Fibre Channel management instance.

This MIB contains eleven MIB groups, as follows.

4.1. The fcmInstanceBasicGroup Group

This group contains basic information about a Fibre Channel managed instance, including its name and description, the Fibre Channel function(s) it performs, and optional pointers to hardware and/or software components.

4.2. The fcmSwitchBasicGroup Group

This group contains basic information about a Fibre Channel switch, including its domain-id and whether it is the principal switch of its fabric.

4.3. The fcmPortBasicGroup Group

This group contains basic information about a Fibre Channel port, including its port name (WWN), the name of the node (if any) of which it is a part, the type of port, the classes of service it supports, its transmitter and connector types, and the higher level protocols it supports.

Each Fibre Channel port is represented by an entry in the ifTable (see below). The tables relating to ports in this MIB are indexed by the port's value of ifIndex.

4.4. The fcmPortStatsGroup Group

This group contains traffic statistics, which are not specific to any particular class of service, for Fibre Channel ports.

4.5. The fcmPortClass23StatsGroup Group

This group contains traffic statistics that are specific to Class 2 or Class 3 traffic on Fibre Channel ports, including class-specific frame and octet counters and counters of busy and reject frames.

4.6. The fcmPortLcStatsGroup Group

Some of the statistics in the fcmPortClass23StatsGroup can increase rapidly enough to warrant them being defined using the Counter64 syntax. However, some old SNMP systems do not (yet) support Counter64 objects. Thus, this group defines low-capacity (Counter32-based) equivalents for the Counter64-based statistics in the fcmPortClass23StatsGroup group.

4.7. The fcmPortClassFStatsGroup Group

This group contains traffic statistics that are specific to Class F traffic on the E_Ports of a Fibre Channel switch.

4.8. The fcmPortErrorsGroup Group

This group contains counters of various error conditions that can occur on Fibre Channel ports.

4.9. The fcmSwitchPortGroup Group

This group contains information about ports on a Fibre Channel switch. For an Fx_Port, it includes the port's timeout values, its hold-time, and its capabilities in terms of maximum and minimum buffer-to-buffer credit allocations, maximum and minimum data field sizes, and support for class 2 and class 3 sequenced delivery. For an E_Port or B_Port, it includes the buffer-to-buffer credit allocation and data field size.

4.10. The fcmSwitchLoginGroup Group

This group contains information, known to a Fibre Channel switch, about its attached/logged-in Nx_Ports and the service parameters that have been agreed with them.

4.11. The fcmLinkBasicGroup Group

This group contains information known to a local Fibre Channel management instance, and concerning Fibre Channel links including those which terminate locally.

5. Relationship to Other MIBs

This MIB is a replacement for two other MIBs: RFC 2837, and the Fibre Channel Management Integration MIB which was originally submitted as an Internet Draft to the IETF's IPFC Working Group, and is now available as [MIB-FA].

5.1. The Interfaces Group MIB

The Interfaces Group MIB [RFC2863] contains generic information about all lower layer interfaces, i.e., interfaces which are (potentially) below the internet layer. Thus, each Fibre Channel port should have its own row in the ifTable, and that row will contain the generic information about the interface/port. The Interfaces Group MIB specifies that additional information which is specific to a particular type of interface media, should be defined in a media-specific MIB. This MIB is the media-specific MIB for Fibre Channel ports/interfaces.

Section 4 of [RFC2863] requires that a media-specific MIB clarify how the generic definitions apply for the particular type of media. The clarifications for Fibre Channel interfaces are as follows.

5.1.1. Layering Model

The Interfaces Group MIB permits multiple ifTable entries to be defined for interface sub-layers, and for those multiple entries to be arranged in a stack.

For Fibre Channel interfaces, no sublayers are defined and a Fibre Channel interface will typically have no other ifTable rows stacked on top of it, nor underneath it.

5.1.2. Virtual Circuits

This Fibre Channel MIB does not deal with virtual circuits.

5.1.3. ifRcvAddressTable

The ifRcvAddressTable does not apply to Fibre Channel interfaces.

5.1.4. ifType

The value of ifType for a Fibre Channel interface is 56.

5.1.5. ifXxxOctets

The definitions of ifInOctets and ifOutOctets (and similarly, ifHCInOctets and ifHCOctets) specify that their values include framing characters. For Fibre Channel interfaces, they include all the octets contained in frames between the Start-of-Frame and End-of-Frame delimiters (excluding the delimiters).

5.1.6. Specific Interface Group MIB Objects

The following table provides specific implementation guidelines for applying the objects defined in the Interfaces Group MIB to Fibre Channel interfaces. For those objects not listed here, refer to their generic definitions in [RFC2863]. (RFC 2863 takes precedence over these guidelines in the event of any conflict.)

Object	Guidelines
ifType	56
ifMtu	The MTU as seen by a higher layer protocol, like IP. That is, when IP is running over the interface, this object is the size of the largest IP datagram that can be sent/received over the interface.

ifSpeed	For 1Gbs, this will be 1,000,000,000; for 2Gbs, it will be 2,000,000,000. If auto-negotiation is implemented and enabled on an interface, and the interface has not yet negotiated an operational speed, this object SHOULD reflect the maximum speed supported by the interface.
ifPhysAddress	The interface's 24-bit Fibre Channel Address Identifier, or the zero-length string if no Address Identifier has been assigned to the interface.
ifAdminStatus	Write access is not required, and support for 'testing' is not required.
ifOperStatus	Support for 'testing' is not required. The value 'dormant' has no meaning for Fibre Channel interfaces.
ifInOctets	The number of octets of information
ifHCInOctets	contained in received frames between the Start-of-Frame and End-of-Frame delimiters (excluding the delimiters).
ifInUcastPkts	The number of unicast frames received,
ifHCInUcastPkts	i.e., the number of Start-of-Frame delimiters received for unicast frames.
ifInErrors	The sum for this interface of - fcmPortLossofSynchs - fcmPortLossofSignals - fcmPortPrimSeqProtocolErrors - fcmPortInvalidTxWords - fcmPortInvalidCRCs - fcmPortAddressErrors - fcmPortDelimiterErrors - fcmPortTruncatedFrames - fcmPortEncodingDisparityErrors plus any errors in fcmPortOtherErrors that were input errors.

ifOutOctets ifHCOctets	The number of octets of information contained in transmitted frames between the Start-of-Frame and End-of-Frame delimiters (excluding the delimiters).
ifOutUcastPkts	The number of frames transmitted, ifHCOutUcastPkts i.e., the number of start-of-frame delimiters transmitted for unicast frames.
ifOutErrors	This is the number of errors in fcmPortOtherErrors that were output errors.
ifInMulticastPkts	These counters are not incremented
ifInBroadcastPkts ifOutMulticastPkts ifOutBroadcastPkts ifHCInMulticastPkts ifHCInBroadcastPkts ifHCOutMulticastPkts ifHCOutBroadcastPkts	(unless a proprietary mechanism for multicast/broadcast is supported).
ifLinkUpDownTrapEnable	Refer to [RFC2863]. Default is 'enabled'
ifHighSpeed	The current operational speed of the interface in millions of bits per second. For 1Gbs, this will be 1000; for 2Gbs, it will be 2000. If auto-negotiation is implemented and enabled on an interface, and the interface has not yet negotiated an operational speed, this object SHOULD reflect the maximum speed supported by the interface.
ifPromiscuousMode	This will normally be 'false'
ifConnectorPresent	This will normally be 'true'.

5.2. Entity MIB

The Entity MIB [RFC2737] contains information about individual physical components and any hierarchical relationship that may exist between them. Any Fibre Channel management instance with a relationship to a physical component (or to a hierarchy of physical components) will have its value of the fcmInstancePhysicalIndex object contain a pointer to the relevant row in the Entity MIB. If

there is no correspondence with a physical component (or said component does not have a row in the Entity MIB), then the value of `fcmInstancePhysicalIndex` is zero. (Note that an implementation is not required to support a non-zero value of `fcmInstancePhysicalIndex`.)

5.3. Host Resources MIB

The Host Resources MIB [RFC2790] includes information about installed software modules. Any Fibre Channel management instance with a correspondence to a software module, will have its value of the `fcmInstanceSoftwareIndex` object contain a pointer to the relevant row in the Host Resources MIB. If there is no correspondence to a software module (or said software module does not have a row in the Host Resources MIB), then the value of `fcmInstanceSoftwareIndex` is zero. (Note that an agent implementation is not required to support a non-zero value of `fcmInstanceSoftwareIndex`.)

"A set of functions that a Fibre Channel Interconnect Element or Platform might perform. A value with no bits set indicates the function(s) are unknown. The individual bits have the following meanings:

other - none of the following.

hub - a device that interconnects L_Ports, but does not operate as an FL_Port.

switch - a fabric element conforming to the Fibre Channel switch fabric set of standards (e.g., [FC-SW-3]).

bridge - a device that encapsulates Fibre Channel frames within another protocol (e.g., [FC-BB], FC-BB-2).

gateway - a device that converts an FC-4 to another protocol (e.g., FCP to iSCSI).

host - a computer system that provides end users with services such as computation and storage access.

storageSubsys - an integrated collection of storage controllers, storage devices, and necessary software that provides storage services to one or more hosts.

storageAccessDev - a device that provides storage management and access for heterogeneous hosts and heterogeneous devices (e.g., medium changer).

nas - a device that connects to a network and provides file access services.

wdmux - a device that modulates/demodulates each of several data streams (e.g., Fibre Channel protocol data streams) onto/from a different part of the light spectrum in an optical fiber.

storageDevice - a disk/tape/etc. device (without the controller and/or software required for it to be a 'storageSubsys')."

7. Acknowledgements

This memo is partly based on the information contained in the original submission of the Fibre Channel Management Integration MIB to the IETF's IPFC Working Group (now available as [MIB-FA]) and obsoletes RFC 2837.

Feedback has been incorporated into this document based on comments from the following: Sudhir Pendse, SimpleSoft; Steve Senum, Cisco Systems; and Kha Sin Teow, Brocade.

10. Security Considerations

There are a number of management objects defined in this MIB that have a MAX-ACCESS clause of read-write:

```
fcmInstanceTextName
fcmInstanceDescr
fcmSwitchDomainId
fcmPortAdminType
fcmPortAdminSpeed
fcmISPortClassFCredit
```

Such objects may be considered sensitive or vulnerable in some network environments. For example, the ability to change network topology or network speed may afford an attacker the ability to obtain better performance at the expense of other network users; setting fcmSwitchDomainId to an invalid value could lead to denial of service in some configurations. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. In particular, these objects provide information on network topology:

```
fcmLinkEnd1NodeWwn
fcmLinkEnd1PhysPortNumber
fcmLinkEnd1PortWwn
fcmLinkEnd2NodeWwn
fcmLinkEnd2PhysPortNumber
```

```
fcMLinkEnd2PortWwn  
fcMLinkEnd2AgentAddress  
fcMLinkEnd2PortType  
fcMLinkEnd2UnitType  
fcMLinkEnd2FcAddressId
```

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPsec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementors consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

11. IANA Considerations

11.1. OID Assignment

IANA has made a MIB OID assignment under the transmission branch. Specifically, transmission 56 has been assigned as the OID for fcMgmtMIB. This sub-identifier was requested because this MIB contains the media-specific definitions that correspond to the ifType value of fibreChannel(56).

11.2. FC Port Type Registry

IANA has established a registry for Fibre Channel Port Types. The registry is split into disjointed subset ranges:

- 1) a 'standard' range for Fibre Channel Port Types that have been standardized by the InterNational Committee for Information Technology Standards (INCITS)'s Technical Committee T11. This range will be subject to the 'Expert Review' and 'Specification Required' policies described in [RFC2434], with the following provisions:

- the Expert Reviewer is to be appointed by the IESG.

- the Expert Reviewer shall obtain approval (or rejection) from INCITS Technical Committee T11 via the chair of that Committee. Rejected values shall not be added to the registry.
- if the addition is approved, the Expert shall advise IANA of how to record the reference to the T11 specification document that describes the newly added port type(s), and that is considered to be the "other permanent and readily available reference" required by [RFC2434].

The initial assignments in the 'standard' range will be as follows:

Assigned Value	Type	Meaning
-----	-----	-----
1	unknown	for use when the type is not known, or is "unidentified" as specified in section 5.1.2.10 of [FC-GS-3]
2	other	used for types without assigned values
3	--	an obsolete value, not to be re-assigned
4	N_Port	see [FC-FS]
5	NL_Port	see [FC-FS]
6	F_Port	see [FC-FS]
7	FL_Port	see [FC-FS]
8	E_Port	see [FC-FS]
9	B_Port	see [FC-FS]
10	G_Port	see [FC-SW-3]
11	GL_Port	see [FC-SW-3]
12	F/NL_Port	see [FC-AL-2]

The above range extends up to a maximum of 9,999.

- 2) a range assigned under the "Private Use" policy described in [RFC2434] for values intended for private use by one party or among mutually consenting parties.
Values in this range extend from 10,000 to 99,999. IANA will not make any allocations from this range.
- 3) values larger than 99,999 are RESERVED.

12. Comparison to the Fibre Channel Management Integration MIB

12.1. Problems with the Fibre Channel Management Integration MIB

The Fibre Channel Management Integration MIB [MIB-FA] had the following major problems:

- It wasn't formatted using SMIV2, which is mandatory.
- The MIB seemed to have been defined with the notion that it would be the only MIB that a Fibre Channel product will require. The notion of an agent implementing just a single MIB was abandoned by the IETF in 1992 as being non-scalable. Rather, a Fibre Channel MIB needed to be another MIB in the continuing series of MIBs defined by the IETF, and thus, it needed to be consistent with its predecessors. In other words, there are existing MIBs that all SNMP agents must support, even if the support of Fibre Channel interfaces is the only functionality that they have. Thus, it was essential that the Fibre Channel Integration MIB contained only objects for information that is specific to Fibre Channel. All objects relevant to non-Fibre Channel environments needed to be removed. This issue applied to a large fraction of the objects defined in the MIB.
- The MIB had some but not complete overlap in functionality with RFC 2837.
- Every SNMP agent must implement the ifTable. The ifTable counters are the MIB objects most well-used by administrators in SNMP management. SNMP agents need to implement a row in the ifTable for each of their network interfaces, including their Fibre Channel interfaces. The IF-MIB requires a media-specific MIB to specify how that type of interface uses the ifTable (see section 4 in RFC 2863). [RFC2837] doesn't do that, nor did the Fibre Channel Integration MIB.
- It incorrectly used the OCTET STRING syntax (instead of Counter32 or Counter64) for counters.

12.2. Detailed Changes

12.2.1. Removal of Sensor-Related Objects

Information about sensors is not specific to Fibre Channel, and therefore should not be in this MIB. (At the time of writing, the IETF's ENTITY MIB Working Group has produced a first draft of a Sensor MIB, see [RFC3433].) This removed the need for:

connUnitSensorTable (and all its contents)
connUnitNumSensors
connUnitSensorStatusChange

12.2.2. Removal of Trap-registration Objects

Information about registering "traps" is not specific to Fibre Channel, and therefore should not be in this MIB. (For similar functionality, see SNMP-NOTIFICATION-MIB and SNMP-TARGET-MIB in RFC 2573). This removed the need for:

trapMaxClients
trapClientCount
trapRegTable (and all its contents)

12.2.3. Removal of Event-Related Objects

Information about generic events is not specific to Fibre Channel, and therefore should not be in this MIB. (For similar functionality, see the Event group in RFC 2819 and the Notification Log MIB in RFC 3014; the SNMP-NOTIFICATION-MIB provides for the filtering of notifications.) This removed the need for:

connUnitEventTable (and all its contents)
connUnitEventFilter
connUnitNumEvents
connUnitMaxEvents
connUnitEventCurrID
connUnitEventTrap

12.2.4. Removal of Inventory-Related Information

Aspects of hardware (physical) components are represented in the Entity MIB (RFC 2737); aspects of software modules are represented in the Host Resources MIB (RFC 2790). Two new objects provide indexing from this MIB into those MIBs: one having the value of PhysicalIndex (or zero) and the other having the value of hrSWInstalledIndex (or zero). These replaced the need for:

connUnitNumports
connUnitRevsTable (and all its contents)
connUnitNumRevs
connUnitPortRevision
connUnitPortVendor
connUnitProduct
connUnitInfo
connUnitSn
connUnitModuleId

connUnitVendorId
connUnitDeletedTrap

12.2.5. Removal of Revision Numbers

The forward/backward compatibility rules of how to evolve MIBs are designed such that MIBs do not have revision numbers. This removed the need for:

revisionNumber

12.2.6. Removal of Other Not FC-Specific Information

Other information was removed because it was not specific to Fibre Channel:

systemURL
statusChangeTime
configurationChangeTime
connUnitUrl
connUnitUpTime
connUnitState
connUnitContact
connUnitLocation
connUnitProxyMaster
connUnitControl
connUnitStatus
connUnitStatusChange

12.2.7. Clean-up of Ambiguous/Obsolete Definitions

Some information in the FC Management integration was obsolete or ambiguous:

statusChangeTime (obsolete)
configurationChangeTime (obsolete)
connUnitTableChangeTime (obsolete)
connUnitStatusChangeTime (obsolete)
connUnitConfigurationChangeTime (obsolete)
connUnitNumZones (obsolete)
connUnitZoneTable (referenced but not defined)
connUnitLinkCurrIndex (badly defined)

12.2.8. Use of an ifTable Entry

The following objects were removed because they duplicated existing IF-MIB objects:

redundant object	existing object(s)
-----	-----
connUnitPortStatCountError	ifInErrors & ifOutErrors
connUnitPortStatCountTxObjects	ifOutUcastPkts & ifHCOutUcastPkts
connUnitPortStatCountRxObjects	ifInUcastPkts & ifHCInUcastPkts
connUnitPortStatCountTxElements	ifOutOctets & ifHCOutOctets
connUnitPortStatCountRxElements	ifInOctets & ifHCInOctets
connUnitPortStatCountRxMulticastObjects	ifInMulticastPkts & ifHCInMulticastPkts
connUnitPortStatCountTxMulticastObjects	ifOutMulticastPkts & ifHCOutMulticastPkts
connUnitPortStatCountRxBroadcastObjects	ifInBroadcastPkts & ifHCInBroadcastPkts
connUnitPortStatCountTxBroadcastObjects	ifOutBroadcastPkts & ifHCOutBroadcastPkts
connUnitPortFCId	ifPhysAddress
connUnitPortControl	ifAdminStatus
connUnitPortState	ifAdminStatus
connUnitPortHWState	ifOperStatus
connUnitPortStatus	ifOperStatus
connUnitPortName	ifAlias
connUnitPortStatObject	ifSpecific
connUnitNumports	ifNumber
connUnitPortStatusChange	linkUp/linkDown

12.2.9. Removed Because of AgentX Difficulty

An AgentX environment [RFC2741] consists of a master agent and several sub-agents. It is not difficult to implement the same MIB in several such sub-agents if all of the MIB's tables have a common index variable as the first auxiliary object in their INDEX clauses. However, any scalars that the MIB contains pose a problem for the AgentX environment. All the (remaining) scalars were therefore removed:

```
revisionNumber
uNumber
systemURL
```

12.2.10. FC Management Instance

The term "connectivity unit" was changed to "FC management instance".

The term "connectivity unit" was not properly defined in [MIB-FA], and its usage provided a confused mixture of indications to the implementor:

- the definition of FcUnitType suggested it was functional;
- the definition of uNumber suggested it was physical;
- the definition of connUnitProduct suggested it was a vendor's product;
- etc.

The common implementation strategy for the "connectivity unit" was which ever grouping provided access to the management functionality the easiest. (One such grouping accommodates a single SNMP agent having multiple AgentX [RFC2741] sub-agents, each supporting a separate implementation of the MIB.)

In fact, this scenario is not new; in practice, a "connectivity unit" will have the same semantics as a management "instance" in other MIBs, e.g., the IPS WG's own iSCSI MIB. For this MIB, its meaning is: "a separable managed instance of Fibre Channel functionality". Given this definition, the "FC management instance" is a better name because it is more accurate and more representative of the definition than is "connectivity unit".

12.2.11. Counter Syntax

All packet and octet counters have been changed to be Counter64's (but Counter32 versions of them are also included for use by old agents). The error counters have been changed to Counter32's. (In the probably impossible, and at most improbable, circumstances that the rate of occurrence of errors, even on a 10Gbs Fibre Channel interface, might wrap faster than an hour, the fact that errors are occurring will almost certainly be apparent from other MIB objects.)

12.2.12. Obsolete/Little-Used Fibre Channel Features

Information relating to Fibre Channel features that are obsolete or not widely-implemented has been deleted. (For more information, see section 6.2.1 and section 6.2.2 of [FC-MI].)

- Class 1 service,
- Intermix Mode,
- Stacked Conn Mode.
- PH version numbers

Note that with support for Class 1 service being deleted, only class 2 now needs F_BSY, F_RJT, P_BSY, and P_RJT counters, and thus they no longer need to be counted for all classes as well as for class 2, and therefore the following objects have been deleted:

```
connUnitPortStatCountFBSYFrames
connUnitPortStatCountPBSYFrames
connUnitPortStatCountFRJTFrames
connUnitPortStatCountPRJTFrames
```

12.3. Name Server Objects

A table of Name Server information was present in the Fibre Channel Management Integration MIB [MIB-FA]. That information is not currently represented in this MIB because this MIB is already quite large, and a set of Name Server objects are expected to be defined in a separate (new) MIB.

12.4. Additional Objects

Support for Class F traffic, including 32-bit octet and frame counters, has been added.

13. Comparison to RFC 2837

This MIB is a superset of RFC 2837, except for the following:

- the fcFeClass1AccountingGroup group is obsolete,
- fcFxFPortConnectedNxPort, fcFxFPortFcphVersionHigh, fcFxFPortFcphVersionLow, fcFxFPortFcphVersionAgreed, fcFxFPortStackedConnModeAgreed, fcFxFPortIntermixSuppAgreed, fcFxFPortCapStackedConnMode, and fcFxFPortCapIntermix are obsolete,
- fcFxFPortBbCredit and fcFxFPortRxBufSize are per attached Nx_Port,
- fcFxFPortBbCreditAvailable is ephemeral,
- fcFeModuleTable is mostly contained in the entPhysicalTable,
- fcFxFPortPhysAdminStatus, fcFxFPortPhysOperStatus, and fcFxFPortPhysLastChange have equivalents in the ifTable.
